Abstract:
Ambrosia causes most pollen allergies in North America. After several Ambrosia species were introduced to Europe, an increase in the incidence of allergy to pollen of these plants has been observed in many countries. The aim of this study was to compare Ambrosia pollen seasons in 2018 in 13 cities located in different regions of Poland: Białystok, Bydgoszcz, Cracow, Drawsko Pomorskie, Lublin, Olsztyn, Opole, Piotrkow Trybunalski, Sosnowiec, Szczecin, Warsaw, Wroclaw and Zielona Gora. The study was conducted by the volumetric method using Burkard or Lanzoni pollen samplers. The pollen season was determined by the 98% method. The earliest pollen season start dates (the end of July) were recorded in Zielona Gora, Bydgoszcz, Opole and Szczecin, while the latest ones in Drawsko Pomorskie and Białystok. The longest pollen seasons occurred in Opole, Szczecin and Zielona Gora (79 days). The highest average daily concentrations of Ambrosia pollen were recorded in Białystok (129 P/m³) and Lublin (99 P/m³), while the lowest ones in Drawsko Pomorskie and Szczecin (4 and 10 P/m³, respectively). The annual pollen sum reached the highest value in Opole (567 pollen grains) and Zielona Gora (555 pollen grains). It can be concluded from the pattern of Ambrosia pollen seasons at the monitoring sites studied that pollen of this taxon originates not only from Ambrosia locations in Poland but also from long-distance transport.

Key words: allergens, pollen concentration, risk of allergy, ragweed, Ambrosia, 2018
Ambrosia pollen is the most frequent cause of pollen allergy in North America [1]. After five American species of this genus were introduced to Europe, Ambrosia pollen allergens have also become a hazard in many countries of the western, central and eastern parts of this continent [2–6]. Ambrosia artemisiifolia is the most widely distributed both in Western and Eastern Europe [7, 8].

Ragweed flowering and pollen release in Poland last from August, and sometimes already from July, until October [2, 9]. Ambrosia artemisiifolia and A. trifida have been found to occur in some regions of Poland, among others in south-west and south-eastern localities [10]. During the 2018 growing season, a new ragweed location was spotted in one of Lublin’s districts. To date, it has been shown that in Poland airborne ragweed pollen originates from local stands and from long-distance transport [5].

In many European countries Ambrosia pollen grains are a persistent cause of allergy-associated respiratory diseases [2], and its fragments have been proposed as the trigger for asthma [4, 11]. Dechamp et al. [12] report that 1–2 pollen grains in 1 m³ of air may induce slight allergic symptoms. However, Jäger [13] determined that 20 pollen grains/m³ are the threshold value of Ambrosia pollen concentration causing allergic rhinitis in sensitive individuals. Richter et al. [14] report that 4–5% of Europe’s population are sensitized to ragweed pollen, whereas Rapijekio [2] claims that in areas where ragweed occurs in large numbers about 8–12% of the population exhibit hypersensitivity to allergens of this pollen.

Aim

The aim of this study was to compare airborne Ambrosia pollen concentrations in 2018 in 13 cities in Poland: Białystok, Bydgoszcz, Cracow, Drawsko Pomorskie, Sosnowiec, Lublin, Olsztyn, Opole, Piotrkow Trybunalski, Szczecin, Warsaw, Wroclaw and Zielona Gora.

Material and method

Measurements of Ambrosia pollen concentrations in the atmospheric air of the above-mentioned cities were carried out using volumetric Burkard or Lanzoni samplers, which operated on a continuous basis. Daily (24 h) pollen counts were recorded. The results were expressed as the number of pollen grains in m³ of air per day (P/m³). The pollen season duration was determined by the 98% method. Start and end pollen season dates, maximum concentration, date of maximum concentration and annual pollen sum were determined. The pollen season pattern was presented in graphs.

When determining the degree of risk of allergy during the Ambrosia pollen season, 5 P/m³ and 20 P/m³ were accepted as the threshold values that may trigger hypersensitivity symptoms, in accordance with the literature data [13, 15].

Results and discussion

In 2018 the Ambrosia pollen season started earliest in Zielona Gora (July 26th) and latest in Drawsko Pomorskie (August 18th) (tab. 1, figs 1–6). In Białystok, Cracow, Sosnowiec and Warsaw, the first pollen grains of this taxon were recorded at the end of the first decade of August (August 8th–10th). In 2016, on the other hand, the first Ambrosia pollen grains appeared two weeks later (August 7th – Lublin, Olsztyn) [16, 17].

In 2018 attention is drawn to the significant duration of the pollen season of the taxon studied, which was from 46 days (Białystok) to 79 days (Szczecin, Opole, Zielona Gora), on average 65 days. The Ambrosia pollen season recorded in 2016 at the same monitoring sites was much shorter and reached 46 days on average [16, 17].

The maximum daily concentration of Ambrosia pollen was recorded in eight cities at a similar time, at the beginning of September (September 7th–8th), whereas in the several other cities in the last 10 days of August (tab. 1). As an exception, in Wroclaw the peak value occurred as late as September 18th. In 2016 the maximum daily concentration of ragweed pollen occurred at the end of the third decade of August almost at all the pollen monitoring sites studied [16, 17].

In 2018 almost all curves representing the Ambrosia pollen season pattern showed the presence of several peaks, similarly as in 2016 [16] and in 2014 [18]. This fact can indicate long-distance pollen transport at different times under favorable weather conditions, which has been demonstrated in several publications [5, 20].

The highest annual total of ragweed pollen grains in 2018 was recorded in Opole (567) and Zielona Gora (555). In 2016 the highest annual total values were also recorded in the same two cities [16].

In 2018 the lowest annual pollen sum was found in Wroclaw, Drawsko Pomorskie and Szczecin (tab. 1). The lowest peak values were recorded in the same cities in the above-mentioned year. The average

Figure 1. Ambrosia pollen count in Bialystok and Lublin in 2018.
Figure 2. Ambrosia pollen count in Opole and Piotrkow Trybunalski in 2018.

Figure 3. Ambrosia pollen count in Bydgoszcz and Olsztyn in 2018.

Figure 4. Ambrosia pollen count in Warsaw and Zielona Gora in 2018.
Worth noting is the six-fold increase in the annual pollen sum in Lublin in 2018 compared to its value recorded in 2016 [16], which may be associated with the existence of new Ambrosia locations in this city. During previous years of the study (2001–2005), the highest Ambrosia pollen concentrations were found in Lublin among all pollen monitoring sites existing in Poland [21]. In 2018 Zielona Gora and Opole showed the greatest risk of allergy due to the largest number of days (36 and 34, respectively) with the exceeded threshold value of 5 P/m³, at which allergy symptoms develop in sensitive patients. Concentrations exceeding 20 P/m³ were recorded with the highest frequency in Lublin and Opole (7 days) as well as in Sosnowiec, Piotrkow Trybunalski and Zielona Gora (5 days). At such concentrations, allergy symptoms occur in most allergy sufferers.

Conclusions
1. In most of the cities, the Ambrosia pollen season in 2018 had a longer duration than in previous years.
2. The maximum ragweed pollen concentration in 2018 was recorded in the last 10 days of August or in the first 10 days of September at most of the study sites in Poland.
3. In Opole, Zielona Gora and Lublin, the risk of Ambrosia pollen-induced allergy in patients was highest.
